Encoding AIS Binary Messages in XML Format for Providing Hydrographic-related Information

Kurt Schwehr and Lee Alexander, Center for Coastal and Ocean Mapping/Joint Hydrographic Center, University of New Hampshire, Durham, New Hampshire (USA)

Abstract
A specification is proposed to enable hydrographic and maritime safety agencies to encode AIS messages using Extensible Markup Language (XML). It specifies the order, length, and type of fields contained in ITU-R.M.1371-1. A XML schema validates the message definitions, and a XSLT style sheet produces reference documentation in 'html' format. AIS binary messages in XML are an effective mean to communicate dynamic and real-time port/waterway information. For example, tidal information can be continuously broadcast to maritime users and applied to a "tide-aware" ENC. The XML format aligns with the type of data encapsulation planned for the IHO Geospatial Standard for Digital Hydrographic Data (S-100).

Résumé
Une spécification est proposée pour permettre aux agences hydrographiques et de sécurité maritimes d’encoder les messages AIS (systèmes d’informations automatisés) à l’aide du langage à balises extensible (XML). Celle-ci précise l’ordre, la longueur et le type de champs contenus dans ITU-R.M.1371-1. Un schéma XML valide les définitions du message et une feuille de style XSLT produit une documentation de référence au format “html”. Les messages binaires AIS en XML constituent un moyen efficace de communiquer des informations dynamiques et en temps réel sur les ports et les voies navigables. Les informations sur les marées peuvent, par exemple, être diffusées en continu aux utilisateurs maritimes et appliquées à une ENC dans laquelle les marées sont prises en compte. Le format XML s’aligne sur le type d’encapsulation des données prévu pour les normes géospatiales de l’OHI pour les données hydrographiques numériques (S-100).

Resumen
Se propone una norma que permita a las agencias hidrográficas y de seguridad marítima codificar mensajes AIS utilizando Extensible Markup Lenguaje (XML). Especifica el orden, longitud y tipo de campos contenidos en ITU-R.M. 1371-1. Un esquema XML valida la definición de mensajes y una hoja tipo XSLT produce documentación de referencia en formato 'html'. Los mensajes binarios AIS en XML son un medio efectivo para comunicar información dinámica y en tiempo real de puertos y/o vías de navegación. Por ejemplo, información sobre mareas puede ser continuamente transmitida a los usuarios marítimos y ser aplicada a ‘aviso de marea’ de ENC. El formato XML se alinea con el tipo de datos encapsulados planificado para el Estándar Geoespacial de Datos Hidrográficos Digitales de la OHI (S-100).
Introduction

Automatic Identification System (AIS) is an autonomous and continuous broadcast system that exchanges maritime safety/security information between participating vessels and shore stations. AIS operates in the VHF maritime mobile band using Time Division Multiple Access (TDMA) technology to be able to meet high broadcast rates, while ensuring reliable and robust operation.

Chapter V of the 1974 SOLAS Convention [1] requires mandatory carriage of AIS equipment on all vessels constructed after 1 July 2002. Implementation for other types and sizes of SOLAS Convention vessels was required to be completed not later than 31 December 2004.

As stated in SOLAS Chapter V, Regulation 19, section 2.4.5, [1] AIS shall:
1. provide automatically to appropriate equipped shore stations, other ships and aircraft information, including ship's identity, type, position, course, speed, navigational status and other safety-related information;
2. receive automatically such information from similarly fitted ships;
3. monitor and track ships; and
4. exchange data with shore-based facilities.

In this regard, the IMO Performance Standards for AIS [2] states that:
The AIS should improve the safety of navigation by assisting in the efficient navigation of ships, protection of the environment, and operation of Vessel Traffic Services (VTS), by satisfying the following functional requirements:
1. in a ship-to-ship mode for collision avoidance;
2. as a means for littoral States to obtain information about a ship and its cargo; and
3. as a VTS tool, i.e., ship-to-shore (traffic management).

Further, AIS should be capable of providing to ships and to competent authorities, information from the ship, automatically and with the required accuracy and frequency, to facilitate accurate tracking. Transmission of the data should be with the minimum involvement of ship's personnel and with a high level of availability. As shown in Table 1, the contents of an AIS message contain detailed information regarding the location and movement as well as other information related to vessel identification, cargo, etc.

AIS enables both ships and maritime safety administrations (e.g., U.S. Coast Guard) to effectively track the movement of vessels in coastal waters (See Figure 1). In addition, AIS can contribute to safety-of-navigation and protection of the environment by providing additional information. This includes meteorological and hydrographic data, carriage of dangerous cargos, safety and security zones, status of aids-to-navigation, and other ports/waterway safety information. It is intended that this information be broadcast from shore-side AIS Base Stations to ships that are underway at-sea or in port.

Binary Message Formats

In May 2004, the IMO issued SN/Circular 236 on "Guidance on the Application of AIS Binary Messages" [3]. More specifically, a set of seven (7) messages were defined with the intent that they would undergo a 4-year trial period. The criteria for selecting the trial messages included a demonstrated operational need, wide cross-section of users (e.g., ships, VTS, pilots, port authorities), and AIS-related messages that had already been developed in terms of format and content.

While it is IMO that defines the content of AIS Messages, it is ITU-R M.1371 that specifies the technical characteristic and the structure of the binary AIS messages [4]. These messages have to be distinguished from Addressed Safety-Related Messages and Broadcast Safety Related Messages both of which allow the exchange of format-free ASCII-text. Binary messages are intended to reduce the need for verbal communications, and to enhance reliable information exchange.

To date, the content of AIS messages have been primarily defined using text tables. Although the tables cover a wide range of information, they are not in a machine-readable format that facilitates rapid AIS binary message generation. While the ITU specifies the technical structure and IMO defined the content (i.e., the "What"), there is a need to define "How" to efficiently generate binary AIS messages. In short, a XML AIS Definition Language provides the method how to create an AIS Binary Message that accomplishes what the tables list.

Table 1: AIS message numbers 1-3 (Class A vessel position report) [Source: ITU-R 1371-1, Table 15a, p. 43.]

**Current AIS Binary Messages**

There are at least four (4) formats that have been developed for the transmission of water level over AIS. One example is the IMO/IALA "Metrological and Hydrological Data" trial binary message specified by IMO [3] and developed by IALA [5]. As shown in Table 2, this type of message contains human-readable text. However, this method of definition can inadvertently lead to unforeseen ambiguities. For instance,
the hydrographic portion contains a range of data types that require scalings and offsets that are not explicitly described. In turn, this may cause problems during software development. An example of a simple ambiguous field is the “Ice” field. The field can have values 0 through 3. It is not clear which number applies to “yes” and “no.” Additionally, if the highest number (3) is taken to be “no data available” or “unknown,” there remains one possible value with an undefined meaning. Another example is that the order of Latitude and Longitude is different than in the rest of the ITU-R M.1371.1 messages [4]. The core messages lists Longitude first, then Latitude.

Using a more orderly and structured format such as XML, provides an effective means to overcome these problems.

**Proposed XML Format for AIS Binary Messages**

It is proposed that Extensible Markup Language (XML) [6] be used to define the binary content (payload) for maritime-based AIS binary messages. By providing a bit-level description in XML, producers of binary messages will be able to more clearly specify messages to software engineers implementing communication systems that must handle AIS messages. The same XML descriptions of messages can be used to generate portions of the human-readable specification document. Using a XML specification allows for rapid development of additional AIS applications such as database interfaces (e.g., PostGIS) [7] and custom graphical user interfaces (e.g., a message construction tool for testing in the reference implementation).

In developing a more robust AIS binary message, there are several goals:

- Specifications that are readable by both humans and machines.
- Allow automated testing and validation of implementations based on the specification.
- Provide specification of the order of fields, length of fields, and type of fields.

  - Specify the scaling and offset to be applied to the field between the application and the AIS network layer.
  - Declare the units of each field when appropriate (e.g., meters, seconds, degrees Celsius).
  - The specification must be independent of programming language (e.g., can be implemented in C, C++, Java, Python).

**AIS XML Definition Language**

To reduce ambiguities and ease the processes of creating AIS software and documentation, the use of an AIS XML Definition Language is proposed. Appendix 1 contains a reference implementation written in Python [8] that gives a sample implementation of code to generate encoders/decoders for an AIS binary message. The AIS XML Definition Language is informally known as the “AIS Binary Decoder Ring.”

The AIS XML Definition Language draws on the best of many existing systems. The most relevant specification is “RFC 1832 - XDR: External Data Representation” [9]. The AIS binary message XML specification is a simplification of RFC:1832 converted to XML with additions that fit the specific requirements of AIS. For example, extensions include:

Table 2: IMO Meteorology and Hydrology Message as specified in IMO SN/Circ.236, Annex 2, Application 1. Also described in AIS, Vol 1, Part 1, Operational Issues, Ed. 1.3. IALA Guideline No 1028, p. 131.
- Bit level field lengths allowing for non-byte align data
- Scaling and offsets of encoded data to increase information density
- Units
- Mandatory human-readable description of each field

AIS XML Definition Language meets all of the goals and relies on industry standard technologies. There are many libraries that support reading and validation of XML documents. XML schemas can be crafted to validate binary message definitions. These schemas might be written in XML Schema [10], Schematron [11], or RelaxNG [12]. Designers can validate draft message definitions using these schema and/or additional validation programs.

Using an AIS XML Definition Language allows for the packaging of test data to validate both encoding and decoding of messages. For each message, a number of example messages can be defined such that the major corner cases are tested by all AIS software vendors. Each example XML test message will contain:
- ASCII encoded binary containing the bit stream represented by “0” and “1” characters
- The NMEA strings as they would be returned by an AIS modem
- The fields broken out with scaling removed

The reference software contains several example XML test messages. They are encoded in a general way such that a new format is not required for each new message type. One practical example would be for Maritime Domain Awareness (MDA). MDA is an initiative within the US Department of Homeland Security that seeks to rapidly process massive amounts of maritime data and information [22]. XML interoperability standards and exchange formats would allow software to access the critical information contained within AIS messages without having to directly comprehend the AIS binary format.

**Basic Format**

The XML specification for one message is encapsulated in a XML “message” tag. The message contains the necessary information to serialize and deserialize AIS message information to and from the AIS binary message payload and the local machine representation used within an application. Messages are wrapped within a XML header and an outer “AIS-binary-message” tag. This tag can contain multiple messages. XInclude [13] allows inclusion of predefined standard structures such as time stamps and positions, which are used in many of the messages.

The message tag contains attributes that specify the name, AIS message number, the Designated Area Code (DAC), and the Functional ID (FID). The attributes for DAC and FID are repeated inside of the XML message definition as fields to facilitate parsing of messages. In order to know what message is being examined, the first bits of the message must be decoded. The ITU 1371 specification of messages 6 and 8 states that the message begins with 16 bits of the application ID. The DAC is the designated area code (e.g., 1 for IMO, 366 for the USA). The FID indicates for which application this data is intended. The IMO trial Met/Hydro format message has a DAC of “11” and a FID of “11.”

For AIS binary messages, AIS message number can be “6”, “8”, or “6 8” depending on if the message is addressed to a recipient or broadcast to all listeners. Message 6 is the AIS Address Binary Message (ABM) where as message 8 is the Broadcast Binary Message (BBM). As the ITU AIS specification is revised, there may be additional message numbers that carry binary message data.

These additional message attributes provide assistance to other applications that might want to develop new AIS technologies that are driven by the XML definition. For example, in Appendix 1, the designer of the AIS XML Definition Language specification for Met/Hydro suggests that displayed Met/Hydro messages be used by the user(s) (i.e., MMSI). The reference Python code uses this to title Google Earth popup messages.

An AIS Binary message is composed of a list of fields. At a minimum, each field contains a name, number of bits, and type attributes. The name is comprised of alphanumeric and underscore characters. Each field is required to have a human-readable description tag. This tag will appear in the “Description” column for all of the generated message documentation (e.g., text documents and web pages).
Each field has XML tags and attributes that specify information about the field and its representation. Each field must have a data encoding type selected from one of the available types listed in Table 3. If a field requires a non-varying specific AIS binary encoded value, it would be listed in a “required” tag. For example, messages that can only be sent as binary broadcast messages will have this value be set to 8 for the “MessageID” field. For fields that can change, it is possible to apply scaling and offsets to the values to pack them into smaller numbers of bits than might be otherwise available. If the number of bits provides a greater range than is needed, the field can be limited using a “range”. For instance, current flow direction requires nine bits for a range of 0-359 degrees. In terms of binary coding this means that 29 (512) is required to achieve at least 359 positions. Usually a particular value is selected to represent that no information is available from the sender for this field. All fields must have a ‘units field’ if units are appropriate. Units might be degrees (as in compass direction), degrees Celsius, meters, seconds, etc.

An example of the end result of using the AIS XML

**Table 3: Binary message field data types**

Definition Language is shown in Table 4. In terms of content, this table contains the same IMO Meteorology and Hydrography messages as Table 2. However, the information used to generate Table 4 is both human and machine-readable – and far easier to implement. Appendix 2 provides an example of a XML message definition converted to a webpage using a XSLT style sheet. This webpage describes the name, number of bits, array length, type, units and a brief description. In turn, this matches the style of other AIS standards specifications.

**Application**

AIS binary messages have a wide range of potential applications that would benefit the hydrographic and maritime user community. In concept, AIS can be an effective means to digitally communicate relevant ports/watersways information related to dynamic and real-time information [14]. One example of a relevant application would be the “Next Generation” Electronic Chart whereby tidal information is continuously broadcast to maritime users either inport or underway and applied to “tide-aware” Electronic Navigation Charts (ENC) capable of accommodating x, y, z, and time [15, 16].

In the USA, the challenges to accomplish these applications are more organisational than technical. The process requires establishing the necessary infrastructure to take the water level information at a particular tide station zone/area from the NOAA Physical Oceanographic Real-Time System (PORTS) [17] and the NOAA CO-OPS [18] systems, convert it into an XML message, and then transmit it via USCG AIS Base Stations to ships in the area. To accomplish the process will require a fair amount of cooperation between government agencies, ECDIS manufactures, and maritime user groups.

Where water levels are transmitted over AIS, finite element modeling software such as TCAI [19] can be used produce a new water surface every six (6) minutes. Potentially, this can be used by both commercial navigators and for hydrographic surveys. Hydrographers would be able to immediately integrate highly-accurate water levels into their processing software to produce better initial results prior to completing the survey cruise. In the future, when electronic chart data is based on gridded data format, each node on the grid could contain a “z” value (i.e., depth) that is made “tide-aware” [20].

Research is ongoing at NOAA, USCG, and UNH as to the best means to convert predicted, forecast, and “nowcast” water levels into an AIS Binary Message format. At present, existing water level messages do not contain the required water level information needed for finite element modeling. However, the

| Total bits           | 352         | Takes 2 slots with 72 pad bits to fill the last slot                       |

Table 4: IMO Meterology and Hydrology messages, 01.11 as displayed from XML definition. Note that fields such as datetime and IAI have been explicitly broken out.
AIS XML Definition Language has potential to allow for rapid prototyping and testing of proposed messages to ensure the final message definition meets maritime users requirement for critical real-time data.

Advantages

Using XML to define Binary AIS Message formats has a number of advantages:

- XML is both human and machine-readable, and provides a central definition that can be transformed into required computer code.
- Although it is the IMO and maritime safety administrations that will decide what should be the content of AIS messages, the XML AIS Binary format provides a means on how current and/or future requirements can be met.
- XML lends itself to the development of additional tools/processes that are open-source and freely-available.
- In addition to maritime/hydrographic applications, XML can be used for River Information Systems (RIS) and other inland/river applications.

Alignment with IHO S-100

The XML formats align quite well with what IHO is planning to do in terms developing a better means of data encapsulation based on the new IHO Geospatial Standard for Digital Hydrographic Data (S-100) [21]. S-100 is the standard intended to be used for the exchange of digital hydrographic data between hydrographic offices, and for the distribution of hydrographic data to manufacturers, mariners and other data users (e.g., environmental management organizations). It was developed so that the transfer of all forms of hydrographic data would take place in a consistent and uniform manner. To date, S-57 Edition 3.0/3.1 has been used almost exclusively for encoding Electronic Navigational Charts (ENCs) for use in Electronic Chart Display and Information Systems (ECDIS). However, there are changing requirements, customers and technology for hydrographic data and as S-57 is intended to support all types of hydrographic data, not solely ENC, it needs to be expanded in order to accommodate these new requirements.

Biographies of the Authors

Dr. Kurt Schwehr is a Research Assistant Professor at the Center for Coastal and Ocean Mapping (CCOM) at the University of New Hampshire. In addition to AIS broadcast applications, he works on a range of projects including developing Chart-of-the-Future technologies, visualization techniques for underwater and space applications, and understanding marine sedimentary processes. He received his PhD from Scripps Institution of Oceanography in marine geology/geophysics, and received a B.S. from Stanford University. Before joining CCOM he worked at the Jet Propulsion Lab, NASA Ames, the Field Robotics Center at Carnegie Mellon, and the US Geological Survey Menlo Park. He is a team member for the NASA Phoenix Mars Lander.

Dr. Lee Alexander is a Research Associate Professor at the Center for Coastal and Ocean Mapping at the University of New Hampshire, and an Adjunct Professor at the University of New Brunswick. He is also a Principle Investigator at the ECDIS Laboratory, University of Southern Mississippi. Previously a Research Scientist with the US Coast Guard and a Visiting Scientist to the Canadian Hydrographic Service, he serves on a number of international committees and working groups dealing with electronic charting and shipboard navigation system standards. He has published over 100 papers and reports on electronic chart-related technologies, and is a co-author of a textbook on Electronic Charting.
